Abstract: This paper presents and analyses “NEP: New Economics Papers”, the current awareness service of the RePEc digital library. NEP is a human-mediated service. New items arriving in RePEc are examined by editors of subject-specific reports. This paper introduces NEP from a conceptual point of view and communicates how NEP fits into the evolving world of digital libraries. We then present summary statistics for the performance of NEP. We pay particular attention to the coverage ratio, and the redundancy of reports. Suggestions for improving the performance of NEP are discussed.

1. Introduction

We are currently witnessing the stone age of digital libraries. This is a time when, for the first time in the history of mankind, collections of purely digital documents are here to rival, if not overtake, the printed library collections as far as size of data and accessibility is concerned. Seen from this angle, it will come as no surprise that the operation of digital libraries, as commonly understood, closely resembles the business of physical libraries. Typically, the digital library is a structured collection of documents made available through an interface of its own, just like the physical library is an organized collection of printed documents that is made available through its own interface, i.e. the library building, shelves, staff etc. This early analogy of the digital library and physical library also implies a distinction between the providers of a digital library, and its

* The authors are grateful to the Joint Information Systems Committee (JISC) of the UK Higher Education Funding Councils for funding the Mailbase and JISCmail services that ran the NEP lists for most of its life. JISC also helped the WoPEc project, a RePEc user service that has continuously supported the development of RePEc. The authors are grateful to Heinrich Stamerjohanns for advice with the graphics package “Grace”, and to Heting Chu and Christian Zimmermann for helpful comments on an earlier version.

users. We can sum up these parallels between physical and digital libraries under the heading of the “legacy model” for digital libraries.

Some recent developments have started to push digital libraries out of the legacy model. Some digital libraries are collections of data that are used through several interfaces operating independently and simultaneously. A classic example is the Open Directory Project, see <http://www.dmoz.org>. It is a directory of the WWW. Its descriptions of web sites, are created by volunteers. They are assembled in a centralized administrative structure maintained by Netscape Communications Corporation. They are then given to search engine to set up subject-tree architectures. These run in parallel with the traditional search interfaces that web search engines provide. More close to the subject matter of traditional libraries, we have another example in the RePEc collection of digital data about economics, see <http://www.repec.org>. One important feature of RePEc is that the collection is both composed and used in a decentralized fashion. That is, there are hundreds of contributing archives, who furnish data about documents, and possibly the documents themselves. They contribute to a collection which has sufficient structure to function like a conventional abstracting and indexing database. This database is then used in many services. This basic *modus operandi* from the RePEc database has more recently been extended and more formally standardized in the Open Archive Initiative’s protocol for Public Metadata Harvesting since the year 2000. This protocol has received wide-spread attention. This is a clear affirmation that the business model pioneered by RePEc in 1997 is an interesting one.

In this paper, we consider another pioneering piece of work coming out of the RePEc community. It is the “NEP: New Economics Papers” current awareness service for new additions to RePEc. This is a human-mediated current awareness service. The idea is that new additions to RePEc are circulated to a group of editors. All editors specialize in a certain subject. These then filter the new entries manually into subject specific reports. Issues of these reports are circulated via dedicated email lists. These lists deal with announcements of papers only, they are not discussion lists.

NEP is technically quite trivial. But it is a pioneering digital library initiative. It goes beyond the legacy model of digital libraries. First it breaks down the separation between users and providers. Some users, the editors, have decided to make a log of their work with the collection public and share it with others. Second, the NEP service is not a pure service provider. It adds information to the RePEc collection. In this sense it goes beyond the legacy model.

In Section 2 we describe NEP more in some detail. There we focus on a historical presentation. Section 3 presents a simple assessment of the operations of NEP to date. There we many focus on the completeness of coverage. Section 4 examines the opposite problem to completeness of

coverage, i.e. redundancy between reports. Section 5 discusses alternative approaches to improve NEP. The final section concludes the paper.

2. History of NEP

The origin of NEP is an email by Thomas Krichel, sent to the, (now defunct) young economists discussion list on 1998-02-04

There is a large-scale development going on to unify the provision of electronic working papers through the internet, called the RePEc project, see <http://netec.mcc.ac.uk/RePEc>. The NBER, the US Federal Reserve Banks and WoPEc are working together in that project, and so are a few others. Currently new additions to that database are circulated through the WoPEc announce mailing list, see <http://www.mailbase.ac.uk/lists/wopec-announce>. This carries announcements for new papers. However the interest of the list is limited by the fact that it carries papers from all parts of the discipline. Despite that fact there are over 700 people on the list.

I am now thinking of opening a series of lists that would operate peer-reviewed announcement. That is each list would be headed by an editor, correspond to a subject that the editor has specified and would only receive announcements of papers that the editor thinks fit into the subject of the list. Each editor would receive a list of new additions to RePEc each week, and would pass on the edited information to the list as (s)he sees fit. All lists put together would be called FERN (like Free Economics Research Network). They would concentrate on delivering contents, rather than administrative information or the names of the big cheeses on the editorial board. Each individual list would be called "FERN reports on XXX", where XXX is the subject stated by the editors. There is no limit to the subjects that could be covered.

This is a call for editors to come forward. As an editor, you would receive a list of additions to the RePEc dataset each week for you to filter, and pass on a selected few to your list. That would not take much of your time, and if you do not feel like sending anything, well then there would be no FERN report on your topic for that week. You will receive absolute power to manage your list as you see fit. You will need to remove dead addresses from time to time, that is all. There are a number of good reasons why the position of editor could be attractive esp. for young economists. First you have to stay on top of the literature anyway, and that is a good way of doing so. Second being the editor of a well edited FERN report series will raise your profile in the profession. Third, you will have the opportunity of work with other editors in far away places and join the wider community working on the free dissemination of research material on the internet.

The label FERN as the Free Economics Network was a pun on the Economics Research Network operated by Social Science Electronic Publishing. After some discussions, the RePEc community advised that it would be better to choose a name that is "independent" of ventures pursued by others, and NEP became the agreed names. The name NEP stands for New Economics Papers. The service has a homepage at <http://nep.repec.org>. A Google query on "NEP" leads to this page as the first hit. At the time of the creation of NEP, the name "NEP" was commonly known among economists to stand for the "New Economic Policy" conducted in the Soviet Union between 1921

and 1928. The suggestion for the name came from Sune Karlsson, a key member of the RePEc team. He was one of the very early editors.

The initial set of editors came from respondents to the initial email, and people from the RePEc community. Editors use a closed email list called nep-editors to discuss their business. Thomas Krichel coordinated efforts to set the operational details. They were contained in a document, known as the York protocol. It was first drafted by Thomas Krichel and Vania Sena in York, UK on 1998-02-14. This document went through several revisions; it was never made publicly available and it is now partially obsolete. The basic concepts of the York protocol are as follows. There is a series of reports on new additions to RePEc. Each report is called a NEP report. Each report contains the new additions to RePEc that pertain to a certain subject, according to the judgment of a person called the report editor. Each report takes the form of a serial, i.e. it has a number of issues. Each issue is dated at the time when it appears. Report editors are free to issue issues of the reports as and when they see fit. Each issue is circulated as an email to a list of recipients, using mailing list software¹. Reports are identified by a handle that obeys to the case-insensitive Perl regular expression `nep-[a-z]{3}`. A special code `nep-all` is reserved for a list of all the papers that have arrived. Users can subscribe to `nep-all`, like they subscribe to any report. But `nep-all` is not a NEP report because it has not been edited to contain only papers of a certain subject. It contains all the papers that are available to the editors.

The York protocol defines the role of a general editor. This is a person who is in overall charge of the substantive aspects of the service. The first holder of this position was John S. Irons, who responded with his intention to the initial email. At the time he was a PhD student in Economics at the MIT and the editor of the economics section of `about.com`. Since October 2000, Bernardo Bátiz Lazo, a business historian from the Open University in the United Kingdom, has continually served as general editor. The general editor accomplishes several important functions. First, (s)he hires editor for the reports and makes sure that they are included in the `nep-editors` mailing list. Usually, the editors are PhD students or junior university faculty. Each editor is responsible for one or more subject areas. The subject area usually corresponds to the editor's research interests, though extensive subject expertise is not required. Nowadays, the general editor examines CVs of candidates for editorship. But there is no formal process of editor selection. Second, s(he) composes `nep-all`. This list used to be generated by computer only. However, since the tenure of Bernardo Bátiz Lazo, the general editor edits this data. This prevents old papers documented in RePEc archives that have just opened to flood the reports. This

¹ Note: the email lists are not the reports. Although each email lists carry the same name as a report, they are simply means by which individual issues of the report are circulated.

operation has to be done “by hand” as the archives may not furnish formal publication dates². Finally, the most important overall task of the general editor is to monitor service quality. Clearly with close to sixty individual reports this is a daunting task. How to come technology can be called in to help is an important issue that we will come back to later.

The technical implementation of NEP has largely been the work accomplishment of José Manuel Barrueco Cruz. Each week, a script calculates the most recent additions for the working papers in the RePEc database³ to compute an issue of nep-all. Once the nep-all issue is inspected by the general editor, another script prepares a proposed report issue. This has the format of an actual issue, i.e. it contains the name of the report, the name of the editor, date of the issue, and, of course the bibliographic information about the new additions. The bibliographic information has two sections. First, a header has titles and authors only. The header section is followed by a body section with the bibliographic information as complete as the RePEc dataset affords, that is, possibly with abstracts and with URLs to full texts. In the early days of RePEc, the full-text links lead directly to the (possibly, but rarely multiple) components of the full text of the paper. Nowadays, they link to a CGI script running on a special machine which then initiates the transfer of the full text. This is done for logging purposes, to assess the importance of NEP in the overall collection of RePEc cross-service usage log by Sune Karlsson’s LogEc project, see <http://logec.hhs.se>. Recently, the identifier of the report has also been added to the CGI script link. This will allow, in the future, for a NEP-wide assessment which NEP reports contribute most to the dissemination of papers in RePEc.

The proposed issues are circulated by email to a group of editors. Each issue arrives at the editor’s inbox with all new papers that have been added to RePEc. The editor then weeds through the report to eliminate all the papers that do not belong to the subject matter of the report. (S)he has to do this both on the summary data and the full data section. A web interface for the composition of reports, made by Sune Karlsson, is also available. For security reasons, it is not publicly advertised. At this time, we are not aware of how many editors use the web interface versus how many message the proposed issue in a text editor.

²The result is not perfect. Christian Zimmermann has informed us that a paper by Aristotle made it into nep-all recently.

³ The RePEc database holds both working paper and article data. Working paper data describe papers that report recent research findings prior to formal publication. Article data concern peer reviewed papers. NEP, at moment only looks at working paper data only. This was a deliberate decision at the time when NEP was set up. The main reason is that the peer review process takes very long in economics. Delays for three years, not counting resubmissions, are common, and with resubmission, it can take five years for a paper to get published. Thus articles are not exactly new papers. In fact research active economists, especially at the top end of the profession, work with working papers, or even drafts that are circulated through private channels.

Setting up the email lists has not been a problem. The system used the UK national academic mailing list services supported by the Joint Information Systems Committee (JISC, see <http://www.jisc.ac.uk>) of the UK Higher Education Funding Councils. JISC first supported Mailbase at <http://www.mailbase.ac.uk>. In August 2000 it stopped supporting Mailbase and supported JISCMail at <http://www.jiscmail.ac.uk> instead. Mailbase run mailing list software built in-house. JISCMail run LISTSERV, by L-Soft international, Inc., see <http://www.lsoft.com>. The move from Mailbase mailing list software to LISTSERV was not a problem. It appears that maintenance effort required by editors is quite small and therefore they absorb the changes quite easily.

On 2001-10-17, Thomas Krichel proposed major reform and development plans for NEP, the so-called Aeroflot proposal, see <http://openlib.org/home/krichel/aeroflot.html>. There is not much point to discuss these plans in much detail here since, at the time of writing, they remain unimplemented. However they contain clues as to what the future may hold for NEP.

In late 2002, Thomas Krichel and Jeremiah C. Trinidad set out implement some preliminary steps for the implementation of the Aeroflot proposal. The key objectives were

- to obtain more local access to the emails as they were sent out;
- to have more control over the interface;
- to shield the service from future domain name changes as the one that occurred when JISC support moved;
- to make it easier to open lists.

In fact the last point was the decisive motivation. JISC are funding the mailing list service for the UK academic community. The general editor (who has been a member of the UK academic community) had to discuss the benefit for the academic community every time when a new mailing list was required. The demand was never refused but the bureaucracy was burdensome.

During late 2002 all the lists from the JISCMail were moved to an installation of Mailman hosted by an account on a machine of Washington University of St. Louis. This machine already hosts the US mirror of the NetEc service and runs the redirection script for NEP downloads. Therefore it was a natural choice for a place to centralize operations. In addition, we downloaded the Mailbase and JISCMail logs in order to have a complete set of logs from the beginning of the NEP era. The data we present in this paper has been gained from the downloaded and unified logs. This has been a very complicated procedure on a technical level. There are a number of

deficiencies in the data⁴. In particular, the dates of emails and the dates on report issues can be erroneous.

3. Overall empirical assessment of NEP

In this section we are doing some simple overall performance evaluation tests on the historic NEP data. Figure 1 shows the history of creation of reports over time. The date of creation (or “birthday”) of a report can be calculated in two ways. First we can use the minimum of the issue dates of all issues. Second we can use the minimum of the email dates of all issues. We calculated both, and then took the maximum of the two numbers. From our own experience this seems a reasonable empirical approach, though, clearly, we do not show a coherent set of birthdays. The history seems discontinuous. More than half the reports were created in the first year. After that phase, in a period of time between April 1999 and August 2001 virtually no report was created. Then several reports appear to be created at the same. In recent days, no new report has been created. The system had first to be stabilized after the move to in-house mailing list hosting using Mailman, in late 2002.

In Figure 2, we look at the input into NEP. Each bar on the graph represents an issue of nep-all. From the graph, there is an impressive increase in the frequency and size of the inflow to NEP. Individual nep-all sizes are subject to important fluctuations, however. There are periods where there has been no report for several weeks. These come as a result of technical difficulties. But even at times of a relatively regular sequence of nep-all issues, there seem to be a high volatility of the size. This is quite problematic, but there is little that NEP itself can do about it. At some times, the number of papers in nep-all reaches the dizzy heights of over 500 papers. In addition, we witness a rapid succession of nep-all issues in recent times. Wading through these piles of documents is by no means a simple task for the editors.

Figure 3 shows the coverage ratio of NEP through time. The coverage ratio is the number of papers that receive at least one announcement in a report, divided by the total number of papers in nep-all. The bar chart shows the coverage ratio of each nep-all issues, one bar per issue. We should expect that the coverage ratio increases over time, as there has been an expansion in the number of lists. But it appears that the coverage ratio is static at best. The number of reports increases over time; but there are more and more papers to be dealt with. In this situation, editors are either overwhelmed and do not perform their job properly, or they become more choosy. Both

⁴ Space constraints prohibit a detailed discussion of these issues here. Interested readers should contact Thomas Krichel.

effects decrease the observed coverage ratio. Note that it should not come as a surprise that the coverage ratio falls off at the end of the period of observation. At that time, the very latest nep-all issues have not yet been filtered into reports.

We can see the impact of the size of nep-all on the coverage quite clearly by graphing size of nep-all and coverage ratio in a cross-sectional rather than longitudinal plot. Figure 4 shows this graph. When nep-all is very small, the fact that a single paper is missing has an important impact on the ratio. Despite this artefact of small numbers, there appears a clear negative relationship between nep-all size and coverage ratio. On this graph, there appear to be a couple of outliers where we reach a high coverage ratio, despite a large nep-all size. They would need to be investigated further. In addition, we could complete the picture by bringing in other factors, in particular the number of lists, in a full regression analysis, and to look at statistical techniques that would allow us to capture the stock effect of a number of large inflows that are coming one after the other.

An alternative way to grasp the coverage ratio of NEP is to look at it from the perspective of individual papers. Each paper may receive zero, one, two etc, announcements. In our Figure 5, we show the potential number of announcements, and the number of papers that receive that many announcements. It is interesting to note that despite the impressive array of reports, the number of announcements is not a multiple of the number of papers. It is also interesting to see that there do not seem to be many papers that are propagated through multiple reports.

Now let us turn away from the issue of papers and turn to the other side of the NEP business, its users. Unlike the logging of papers, there has not been a logging of users subscribing and leaving mailing lists. Such logging only started in early 2003. One of the benefits from moving the system to a computer under direct control of the NEP technical team is that such logging is now rather straightforward. At this stage, we log the users of all reports once a month.

Figure 6 shows potential numbers of reports a user may read to versus the number of user who read that number of reports. It is interesting to see that more than half of all users subscribe to one report only⁵. The users are more report-specific than the papers are⁶. This is an important clue for the evolution of NEP. It suggests opening more reports as a way forward to enlarge the readership of NEP.

4. Measuring the redundancy of reports

⁵ The fact that the number three has a local peak has is the so-called “Leitao” effect, named after Joao Leitao, the editor of three NEP lists who, as a professor, has encouraged his students to subscribe to his lists.

⁶ Note that there are some pranksters who have subscribed to 30 or 50 reports, but these are exceptions that we have not considered in the graph to concentrate on the more relevant figures in the beginning of the scale.

The development of NEP was not an exercise of careful planning to achieve full coverage from the outset. Instead, reports have opened as founding editors volunteered to edit them. When the funding editor retired, a replacement was readily available from the list membership. In this section we are looking at an objective measure for overlap between reports. This is what we refer to as redundancy.

The basic idea is a simple one. An announcement of a paper p on a report r is redundant to the extent that there is a user of report r , who subscribes to another report r' where paper p is announced too. To fix ideas, imagine, as an example, two reports that are identical in the sense that they have the same papers announced in them. Provided that they do not have an overlap in readership, they are not at all redundant. Or, to take another extreme case, consider two reports with the same users. They are not at all redundant provided that they announce different papers all the time. Only the occurrence of common users and common papers make reports redundant. Thus, redundancy between reports r and r' is the fraction of papers of report r that also appear in r' multiplied by the fraction of users of report r who also read report r' . Since the redundancy between two reports is a multiplication between two percentages, it is a small number. The redundancy of a report is the sum of the redundancy between itself and all the other reports. Thus, while the redundancy between two reports is a small number, the total number of redundancies between a report and all the other 57 reports ends up adding up.

In Table 1, we list report identifiers in the first column, and usefulness in the second column. We define “usefulness” as 100% minus the redundancy of the report expressed in percentage. We have ordered the list by usefulness in order to list the least redundant report first. The rest of the columns show the birthday of the report, the number announcements it has issued since birth, the number of subscribers, and the subject of the report. The main purpose of these additional numeric data is to show that there is no obvious way the usefulness of a report can be directly linked to its age or its size in terms of users or papers. Redundancy is an important feature of the reports at the bottom of the table. These will require the attention of the NEP management.

Two remarks are on order here. First the measurement uses subscriber data form 2003-06-01, but relies on data for the announcements of papers since report birth. To precisely measure redundancy we need to have data on which users receive precisely which announcements. This requires continuous time monitoring of the mailing list. We are not aware of how this can be done. While precise measuring is difficult, we could, in the future, do a better job than we have done here if we accumulate user data over many instances in time.

Second, the proof of the pudding is in the eating. Even if a report is redundant, it can still bring an important contribution because it can be a source of many full-text downloads of papers. In his paper, we have not looked at download data. This remains to be done.

5. Improving the operation of NEP

This review has focussed on the history of NEP and then examined in more detail two intuitive measures of the success of the system, the coverage ratio, and the redundancy. In looking at the coverage ratio, we have been mainly interested in the idea that we want to achieve comprehensive coverage. The idea of comprehensive coverage may not be appealing in a situation where the quality of submitted documents is doggy. But in the RePEc case, it is institutional archives that submit papers. Not every paper is a major scientific breakthrough, but if the only 70% reach one of the reports then we do have a serious problem of coverage.

There are many ways by which we can try to improve the coverage ratio. First, we need to lean on editors who are not doing a proper job. This involves calculating immediacy indexes. These are average delays between the email time of a paper in a report and the time of appearance of the same paper in nep-all. At the outset for the work on this paper, we wanted to report such figures in this paper; but the unreliable nature of the historical date data made it too difficult. Immediacy indexes research will have to be conducted in the future.

In order to cope with large inflows of papers, we can first think about a job-sharing protocol that would allow spreading the load of editing between different people. The York protocol explicitly introduced editorial teams but made no formal provision for job sharing. A second way to ease the workload on editors would be to either smooth out or restrict the number of items in nep-all. At the moment, we have all working papers flowing in. We could restrict this only to working papers that are freely available online and for which we have secured the correctness of the full-text URLs. Such a procedure has been proposed on the nep-editors list but no agreement could be reached on a way forward.

A third approach to reducing workload would be to introduce an editorial hierarchy. A hierarchical NEP would have first-tier editors who make decision on broad topics, and then leave it to second-tier editors to make decisions that would be communicated to final users only. While this idea has some intuitive appeal, it has many drawbacks. First, it would mean that the responsibility for reports is dissolved. Second-tier editors could blame first-tier editors for delays. Second, there is no good overall subject classification scheme to be used. Even if there were such a classification, implementing it now would mean revising the entire structure of NEP reports.

This would damage the efforts of the best editors to build a brand name for their product. The best editors are the people we can the least afford to lose. Thus, while hierarchy is a good scheme to work on at the outset of a current awareness system, it is no use as a proposal for reform.

Therefore, with an unchanged lists structure, opening more reports could be a good idea. If there are many specialized lists, the editors could always take a narrow view of the subject, especially if they are aware that editors of surrounding reports may pick up a paper that they are not sure about. The only drawback is that, from a user's point of view, someone who is new to NEP will have a harder time figuring out what reports to subscribe to.

Redundancy calculations are a good way to examine the structure of provision. Unfortunately it does not give us a glimpse for the gaps in the coverage. However, is it quite likely that highly specialized reports will be less redundant, and so will be reports that reach a special audience. Editors will have to be advised that if their contents is not very specific, they need to search for a special audience. They can do that by clever advertising. But from the analysis conducted here it seems that the creation of more specialised reports, without initial concern for overlap, seems to be a good way forward for NEP.

6. Conclusions

NEP is a simple, yet innovative effort. It pushes way beyond the legacy model of digital libraries. First, the users do not need to contact the library, instead the library comes to them, or, more specifically, to their email boxes. Second, NEP has "recent changes" mode of operation that can not be achieved through searching the web with a tool like Google. At a time when users are heavily turning to search engines to satisfy their information needs, NEP shows a distinctive advantage of human information organization over totally machine-processed approach. Third, NEP is another fine example of the RePEc ideal that with coordinated, decentralized volunteer efforts, great things can be achieved in the digital library field. Just imagine that the service would be provided through a "Library of Congress style" classification apparatus. We shudder at the thought of how much more costly this would be in both monetary terms and in time delays.

Finally, and most importantly NEP is an attempt to cross over the divide between users and providers of a digital library. One set of users, the NEP editors, have agreed to make the result of their usage of the digital library, the scanning of the lists of new additions, publicly available. The editors are therefore both users of the digital library as well as providers to it. While a lack of separation between users and providers is part of some Internet services, such as email lists, and personal web logs, it has hitherto received relatively little attention in the digital library literature.

We think the digital library community should pay more attention to the potential of digital libraries to act as community tools. More generally, we firmly believe that the way forward for digital libraries lies more in the “animation” of the contents through user efforts, than in the aggregation of static contents in whatever sophisticated ways this can be done. In this paper, we have presented some of the trials and tribulations we had with a pioneering system. Implementers of similar system will be well advised to examine these issues before they are doing ahead with them.
